

What factors affect the energy storage capacity of an inductor?

The energy storage capacity of an inductor is influenced by several factors. Primarily, the inductance is directly proportional to the energy stored; a higher inductance means a greater capacity for energy storage. The current is equally significant, with the energy stored increasing with the square of the current.

How do inductors store energy?

In conclusion, inductors store energy in their magnetic fields, with the amount of energy dependent on the inductance and the square of the current flowing through them. The formula $W = \frac{1}{2} L I^2$ encapsulates this dependency, highlighting the substantial influence of current on energy storage.

What are some common hazards related to the energy stored in inductors?

Some common hazards related to the energy stored in inductors are as follows: When an inductive circuit is completed, the inductor begins storing energy in its magnetic fields. When the same circuit is broken, the energy in the magnetic field is quickly reconverted into electrical energy.

How does Linear Technology affect inductor energy storage?

While one inductor's current is increasing, the other's is decreasing. There is also a significant reduction in the required inductor energy storage (approximately 75%). The inductor's volume, and therefore cost, are reduced as well. See Linear Technology's Application Note 77 for complete details.

Why is an inductor lossless?

Without the internal resistance, the inductor is lossless because it cannot produce heat or light from the available energy. Therefore, all the energy supplied by the source ends up being stored in the generated magnetic field - exactly how energy is stored in rubber bands when stretched.

What happens when an excited inductor loses connection to the supply?

When an excited inductor loses connection to the supply, it quickly breaks its magnetic fields and tries to continue the connection to the supply with the converted energy. This energy can cause destructive arcing around the point where the connection is lost. Thus, the connectivity of the circuit must be continuously observed.
