

Is high temperature thermal energy storage a good option?

High temperature thermal energy storage is one promising option with low cost and high scalability, but it is hindered by the inherent complexity of simultaneously satisfying all of the material requirements. Here we design a class of ceramic-carbon composites based on co-optimizing mechanical, electrical, and thermal properties.

Can self-heating SSBs be scalable to commercial battery packs?

We demonstrate a fast, non-invasive self-heating method that warms SSBs to optimal operating temperature in under a minute using ultra-high-frequency electrical pulses. This approach requires no structural changes, adds minimal energy cost, and is scalable to commercial battery packs.

Can self-heating SSBs reduce energy consumption?

Using an experimentally validated model, pack-level simulations predict fast heating (50 K/min) and minimized heating energy consumption (less than 4%). Without any modification of the materials or structure of the batteries, our non-intrusive self-heating strategy potentially enables SSBs to discharge more than 2-fold energy in 25°C ambient.

Can SSB batteries be self-heated?

Taking advantage of their strong temperature-dependent ionic conductivity, here we introduce ultra-high-frequency (greater than 105 Hz) self-heating (UHFSH) of SSBs, which can rapidly warm up the batteries from room temperature to operating temperature (~65°C) in less than a minute.

What is the temperature ramp rate of AC self-heating?

The temperature ramp rate of AC self-heating for LIBs is ~0.1°C/s, which is significantly faster than conventional external heating. However, this rate remains too low for practical applications, as it requires over 5 min to reach the ideal ionic conductivity necessary for battery discharge and vehicle start-up.
